

What a Czech industrial electricity bill is made of

And how much of it a supplier can actually compete on. Czechia benchmarked against its five neighbouring markets and the EU average.

Two thirds of the bill is ours to price

Mid-size industrial consumers (2 000-19 999 MWh a year), 2025-S2, excluding VAT.

+64.9%

against 2021-S2, after peaking in 2023-S1

THE FINDING

Czech industry pays 16.4 cents per kWh — the lowest of the six markets compared, 15% below Germany, though still +2.5% against the EU average.

The level matters less to a supplier than the composition. 66% of that bill is energy and supply — the highest share in the group, against 46% in Poland. Network charges and taxes are set by the regulator and the state and are identical whichever supplier a customer signs with.

Prices came down, but not all the way back

Business electricity price, band 2 000-19 999 MWh, since 2015.

WHAT THIS SHOWS

Czech prices peaked in 2023-S1 at 18.3c, +84.7% on 2021-S2.

They have since fallen 11%, but remain +64.9% above pre-crisis levels.

Czechia moved less violently than its neighbours through 2022-2023. That is worth saying to a customer comparing offers across the border.

Czechia is the cheapest of its neighbours

Price per kWh, 2025-S2, excluding VAT.

WHAT THIS SHOWS

Czechia 16.4c against Germany 19.2c — a gap of 15%.

The EU average sits below Czechia. So 'cheap' here means cheap against the neighbours a Czech plant competes with for orders. Against Europe as a whole it is a little above the middle.

Where the money in the bill goes

Price split into energy & supply, network costs and taxes, 2025. Countries ordered by the share a supplier controls.

WHAT THIS SHOWS

In Czechia 66% of the bill is the commodity. In Poland it is 46%: nearly half that bill is tax, and no supplier can discount it.

A 10% cut on the commodity is worth 6.6% off a Czech customer's total bill, against 5.3% in Germany.

Big customers get less of a discount here

Price by annual consumption band, 2025-S2. Measured between < 20 MWh and 70 000-149 999 MWh, the largest band every country reports.

WHAT THIS SHOWS

Across the EU the large band pays 59% less per kWh than the smallest. In Czechia the gap is 34%.

The Czech curve also turns back up: consumers above 20 000 MWh pay more per kWh than the 2 000-19 999 MWh band, the only market here where that happens at that point on the curve.

Czechia does not report the >= 150 000 MWh band at all, so its very largest consumers are invisible in this data.

What this changes for how we price

Three things follow for anyone selling electricity to Czech industry.

01

Price competition works better here than next door

With 66% of the bill in the supplier's hands, a discount reaches the customer's total cost more directly than in Poland (46%) or Germany. The same headline discount buys more visible saving — and costs the same margin.

02

The largest consumers are the exposed segment

The Czech size curve is flat — 34% between the smallest and largest comparable band against 59% EU-wide — and above 20 000 MWh it turns back up. Large industrial accounts get less volume benefit than their EU peers, and they are the group most able to tender across borders.

03

A German parent needs a different argument from everyone else

Czechia is 15% below Germany but +2.5% against the EU average. The credible argument to a German-owned plant is the cross-border gap; the credible argument elsewhere is that Czech prices moved less through the crisis.

How the numbers were made, and where they stop

Every figure here is computed from the cached Eurostat responses in this repository and can be reproduced with one command.

OBSERVATIONS USED

2,775

electricity and gas prices, 2007 onwards

COMPONENT RECONCILIATION

0.8%

median gap between components and the headline series

IF THAT CHECK IS SKIPPED

21%

how far the naive component sum overstates the price

HOW THE NUMBERS WERE CHECKED

- Prices exclude VAT: VAT is recoverable for a business, so the VAT-inclusive series overstates what a company pays.
- The component breakdown is annual, the price series half-yearly; the two were reconciled before anything was built on them.
- Eurostat's tax total already contains VAT. Subtracting it is the difference between a 0.8% and a 21% error.
- Raw API responses are cached in the repository, so the numbers are reproducible even after Eurostat revises a series.

WHAT THIS ANALYSIS CANNOT TELL YOU

- These are national averages. An individual contract depends on the load profile, the hedging strategy and the date it was signed.
- Band boundaries are consumption-based, so a country's mix of industry affects its average within a band.
- Czechia does not report the $\geq 150\,000$ MWh band, so size comparisons stop at 70 000-149 999 MWh — the largest band every country publishes.
- Half-yearly data cannot show what a spot-exposed customer paid in a particular month.
- Nothing here says what any supplier's margin is; the commodity share is what a supplier prices, not what it earns.
